# PureFire ${ }^{\circledR}$ PFW Series <br> Hot Water Supply Boiler Sizing Guide 

## $\triangle$ NOTICE

PB Heat, LLC provides the following information as a courtesy to our customers to aid in the sizing of hot water systems. The application of this data is the responsibility of the customer or engineer specifying the equipment.

## Purpose:

This sizing guide is intended to provide a general method of sizing hot water supply boilers in conjunction with hot water storage.

## Step 1: Determine maximum possible demand

Determine the quantity \& type of fixtures to be supported by the hot water supply system. Use manufacturer specifications for typical fixture usage and flow rate to determine the hourly usage for each fixture.
For example, using a shower head that is designed to provide a maximum of 1.5 gpm of water at 60 psi for an estimated average shower time of 12 minutes will use 18 gallons of hot water. Therefore, using 18 gph per fixture will be a reasonable estimated usage for each shower head.
Table 1 shows typical hot water fixture demand values for various types of buildings. Note that the source of the values predates low-flow fixtures and appliances mandated by the U.S. federal energy efficiency standards in 1992.

Table 1: Hot-Water Demand per Fixture for Various Types of Buildings

| 20 | STORAGE CAPACITY FACTOR ${ }^{\text {b }}$ | 1.25 | 0.90 | 1.00 | 0.60 | 0.80 | 1.00 | 2.00 | 0.70 | 1.00 | 1.00 |
| Note: Data Sources predate low-flow fixtures and appliances. <br> ${ }^{\text {a }}$ Dishwasher requirements should be taken from this table or from manufacturers' data for model to be used, if known. |  |  |  |  | ${ }^{b}$ Ratio of storage tank capacity to probable maximum demand/hr. Storage capacity may be reduced where unlimited supply of steam is available from central street steam system or large boiler plant ${ }^{\text {c }}$ Whirlpool baths require specific consideration based on capacity. They are not included in the bathtub category. |  |  |  |  |  |  |

The following example shows how to determine the maximum possible demand for a 30 unit apartment building based on the number of fixtures using hot water:

| 50 Lavatories | x | 2 gph | $=$ | 100 gph |
| :--- | :--- | ---: | :--- | ---: |
| 30 Showers | x | 30 gph | $=$ | 900 gph |
| 30 Kitchen Sinks | x | 10 gph | $=$ | 300 gph |
| 30 Dishwashers | x | 15 gph | $=$ | 450 gph |
| 10 Laundry Tubs | x | 20 gph | $=$ | 200 gph |
| Possible maximum demand |  |  | $=$ | $\mathbf{1 , 9 5 0} \mathbf{~ g p h ~}$ |

Therefore the maximum possible demand is $1,950 \mathrm{gph}$. However, it is unlikely that all 30 units will be using all hot water fixtures at once so, in step 2 , we will apply a demand factor to this total.

## Step 2: Apply Demand Factor

Apply a demand factor, from table 1 , row 19 , based on the type of building to which the sizing is to be applied. This is the probable maximum demand.

Following along with our apartment building example, we use a demand factor of 0.30 based for this type of building.

$$
\text { Probable maximum demand } \quad=\quad 1,950 \mathrm{gph} \times 0.30=585 \mathrm{gph}
$$

Next, we will apply a storage capacity factor.

## Step 3: Apply Storage Capacity Factor

Apply a storage capacity factor, from table 1 , row 20 , based on the type of building to which the sizing is to be applied. This value will be used to size the hot water supply boiler and storage tank. Tradeoff between boiler recovery capacity and tank size will be addressed in Step 4.

For our Apartment house example, we will apply a storage capacity factor of 1.25 gallons per gph.

Delivery Capacity

$$
=\quad 585 \mathrm{gph} \times 1.25 \frac{\mathrm{gal}}{\mathrm{gph}} \quad=\quad \mathbf{7 3 1} \text { gallons }
$$

## Step 4: Determine Peak Usage Demand Period and apply

Determine the peak usage demand period for the hot water supply system. For systems in which the peak demand lasts for 1 hour or less, such as some dormitories, the $1^{\text {st }}$ hour capacity should be used (table 2 a for PFW-200 and table 2 b for PFW-399). Buildings, such as hotels, with typical peak demand periods between 1 and 2 hours should be sized according to the $2^{\text {nd }}$ hour capacity (table 3a for PFW-200 and table 3b for PFW-399). Buildings with peak demands between 2 and 3 hours should be sized using $3^{\text {rd }}$ hour capacity (table 4 a and 4 b). The building owner should be consulted regarding the water usage patterns for the occupants.

In our example, assuming a 2 to 3 hour peak demand period, we can use table 4 a to determine the storage tank requirement if we use a PFW-200 boiler. If the inlet water is $40^{\circ} \mathrm{F}$ and the water is stored at $140^{\circ} \mathrm{F}$ then we can use a $\Delta \mathrm{T}$ of $100^{\circ} \mathrm{F}$.
From table 4a:

- Selection 1: PFW-200 with one 119 gallon storage tank This can be used since the $3^{\text {rd }}$ hour rating of 742 gallons exceeds the 731 gallons required.
Using table 4b:
- Selection 2: PFW-399 boiler with one 60 gallon storage tank

This is more than adequate for this application since the $3^{\text {rd }}$ hour capacity of 1385 exceeds 731 gallons. In fact, this combination would also be acceptable if the peak demand period were between 1 and 2 hours (table 3 ) since the $2^{\text {nd }}$ hour rating is 938 gallons.
We can also calculate the $3^{\text {rd }}$ hour rating as follows:
hours $\times$ recovery cap. $+(\#$ of tanks $) \times($ tank storage volume $) \times($ usable capacity factor $)=$ capacity Rating

- Selection 3: For a PFW-200 with two 80 gallon storage tanks:

$$
3 \mathrm{hr} \times 220 \mathrm{gph}+(2) 80 \mathrm{gal} \times 0.70=772 \text { gallons }
$$

* The capacities shown above are based on a usable tank volume of $70 \%$. Consult the tank manufacture for the actual usable volume of tanks.
The calculations used for the capacities above follow:

```
1 st hour capacity = recovery rate + usable volume
    For PFW-200 with 100'F rise and an 80 gallon tank: 220 gph + 80 gallons }\times0.70=276 gallo
2 nd}\mathrm{ hour capacity = 2 }\times\mathrm{ recovery rate + usable volume
    For PFW-399 with 100'F rise and a 119 gallon tank: 2 }\times448\textrm{gph}+119\times0.70=979 gallo
3rd}\mathrm{ hour capacity = 3 <recovery rate + usable volume
    For PFW-200 with 80'F rise and two 119 gallon tanks: }3\times275\textrm{gph}+2\times119\times0.70=990 gallon
```
